# Uniprocessor Architectures

- The von Neumann Architecture

In this lecture:

- The **von Neumann architecture**: what is it, why is it useful?
- The main **components** of the architecture: their functions and how they are **connected**.
- Variants like the **Harvard Architecture**

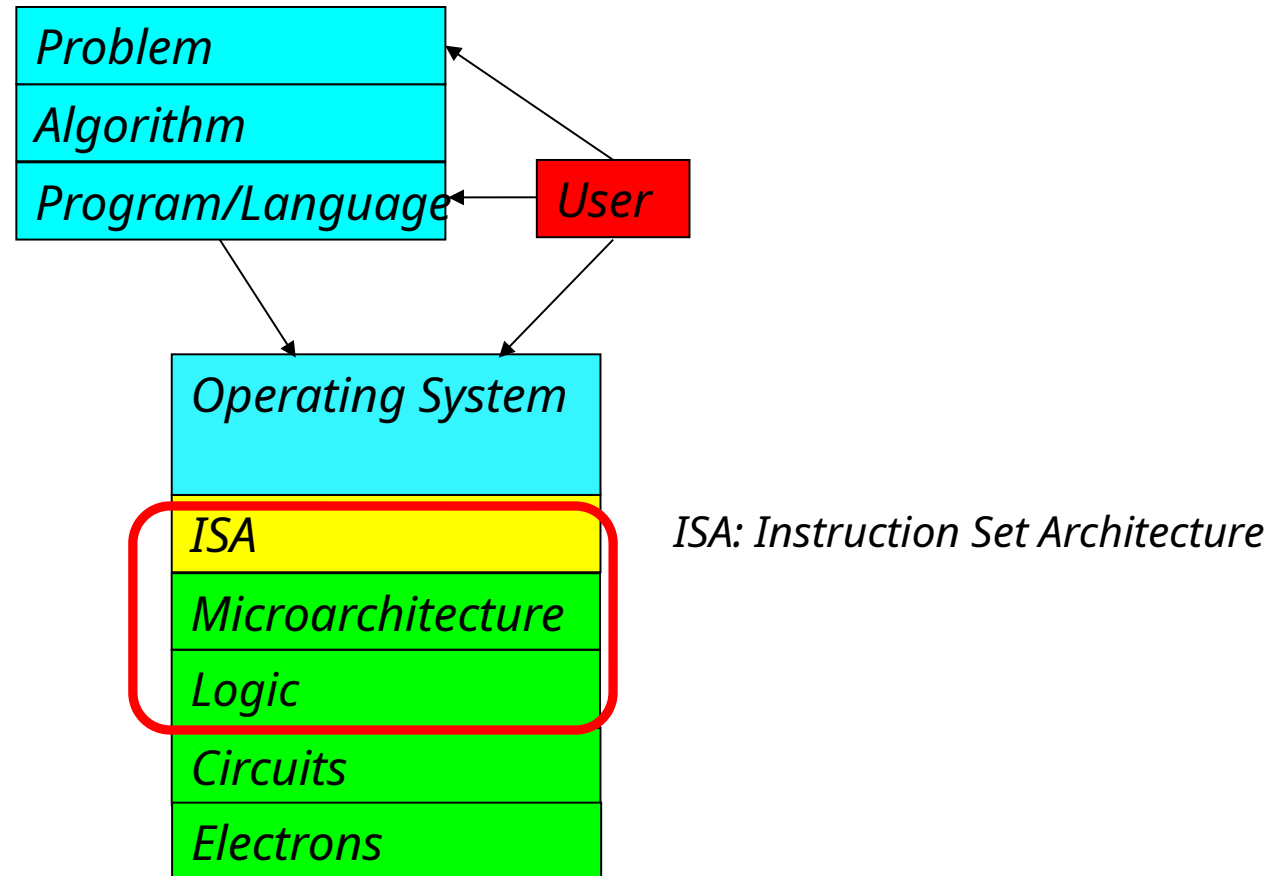

# The von Neumann Architecture

Recall: we need to study architecture at the right *level of abstraction*.

A problem:

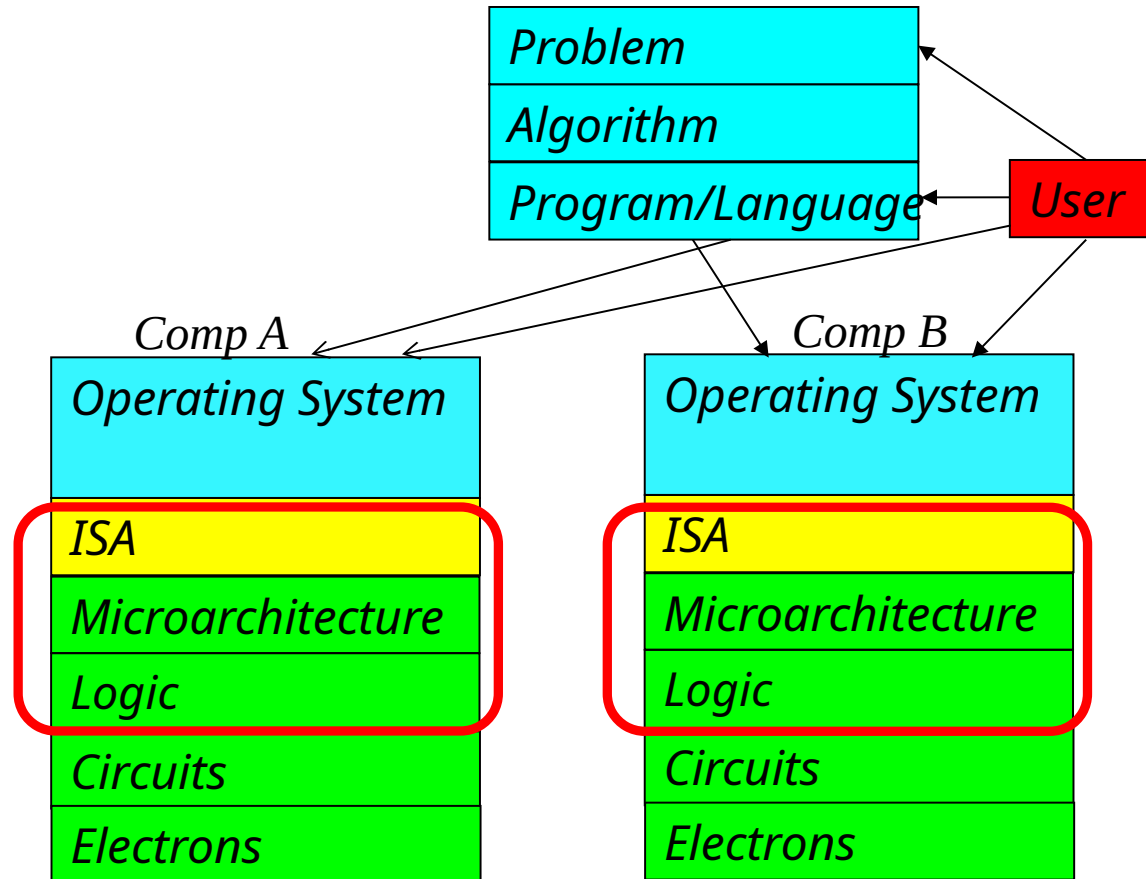

- Programmers and language designers need to know *in essence* how the computer will execute their program.
- But many of the *details of execution* are *less important*.
- ...and we want to be able to run the *same program* on a variety of *different machines* anyway.

# The von Neumann Architecture

Solution:

Virtually all single processor machines correspond to a single *architecture* or *idealization* of a computer, proposed by John von Neumann:

**The von Neumann Architecture.**

This *abstracts from* (hides) the details of particular machines, and reveals their **common structure**.

It is also the basis of other, more particular abstractions, allowing execution of the same program on different platforms

John von Neumann (1903 Hungary - 1957 USA)

Mathematician, physicist, computer scientist, and polymath

Found time between seminal contributions to:

- Set theory
- Game theory
- Quantum Mechanics
- The “Manhattan” project
- ....

to describe the fundamental computer architecture still the basis of most modern processors.

He proposed this architecture for the EDVAC computer though it was based on work by Turing, Eckert and Mauchly

## The von Neumann Architecture: Data Processing

The *arithmetic and logic unit (ALU)* is where computational operations are carried out.

To carry out an operation we need:

- a) An *operation* specification (e.g. add)
- b) Data or *operands* to operate upon

## The von Neumann Architecture: Control

The ALU alone is not automatic. Operations and operands must be supplied in the correct sequence and at the appropriate times. A *control unit* is added to do this:

## The von Neumann Architecture

The main activities of the control unit are as follows:

- To **determine** the operation to be performed;
- To **select** the correct **operands** and make them available at the right time;
- To **perform** the **operation** on the **operands** by supplying the correct control data to the ALU; and
- To determine the **next** operation to be performed!

It is thus the control unit that renders the digital data-processor **automatic**.

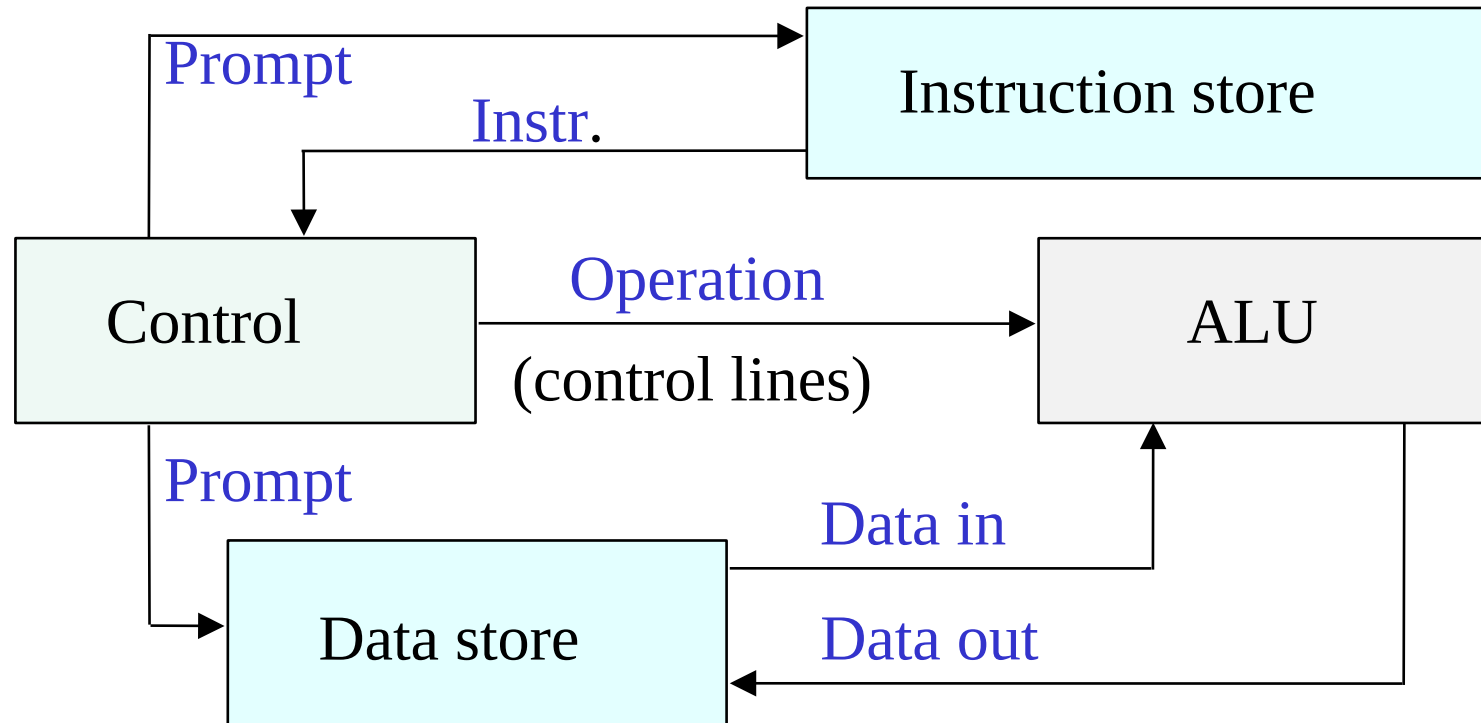

## The von Neumann Architecture: Data

- What form is this data and where does it come from?
- We assume it is *digital* (*exact*) in form, and can be *stored* and *retrieved* in a *data store* unit in response to a stimulus from the control unit.
- If data store and the control unit work fast enough the ALU can be kept in *continuous* operation.

## The von Neumann Architecture

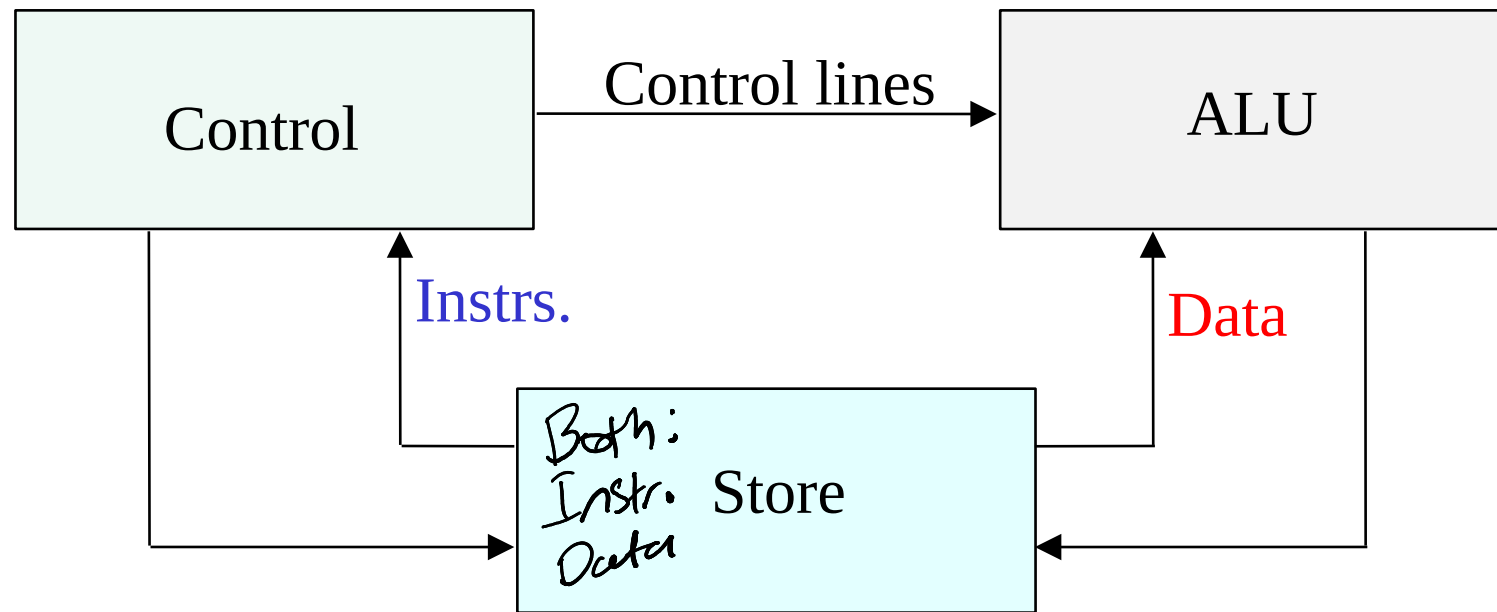

Q: Where does the operation information come from?

A: An *instruction store*!

## The von Neumann Architecture: Store

Manipulating code as data is a powerful programming technique - the two stores are **combined** into a single unit:

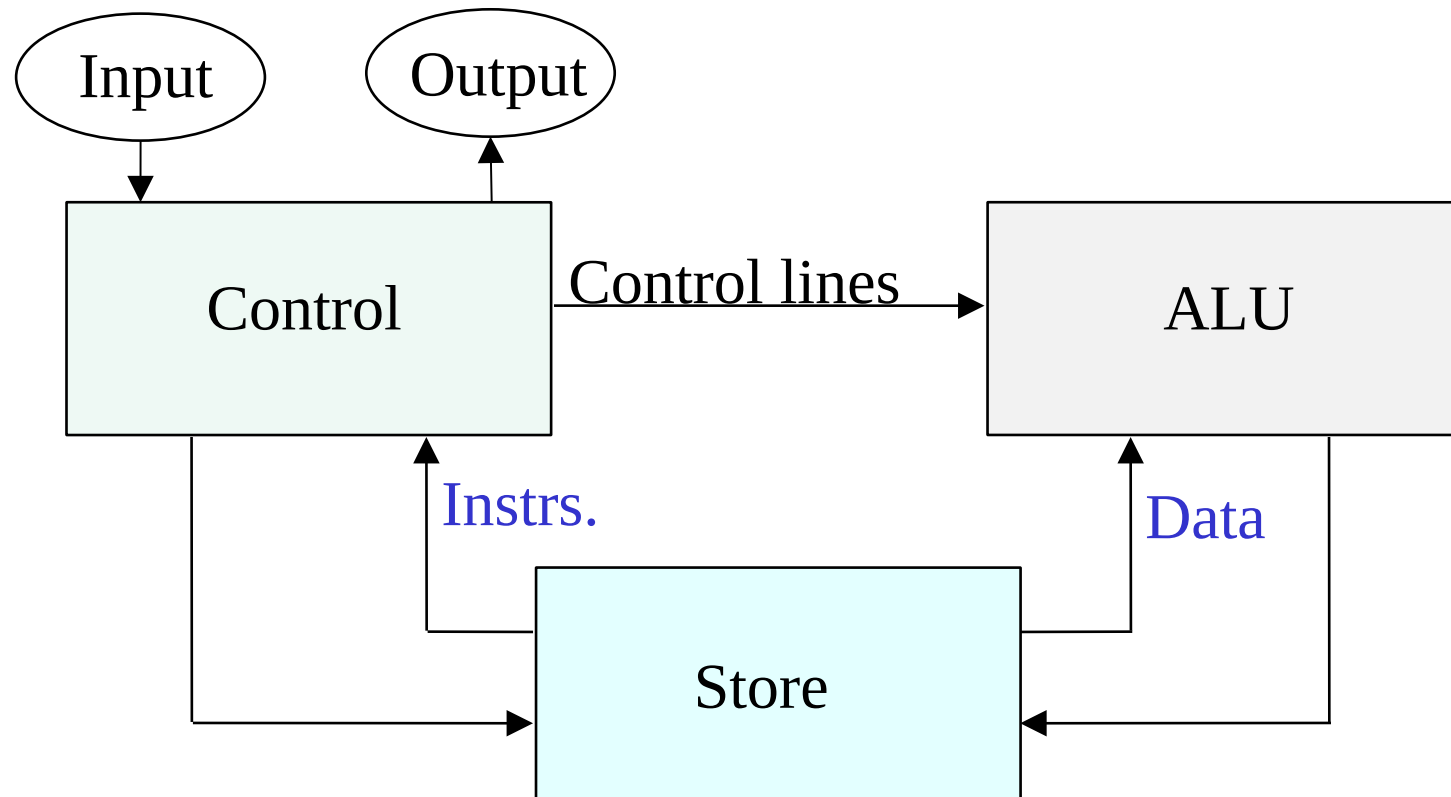

John von Neumann defined an architecture which uses the same memory both to store programs and data: virtually all contemporary computers use this architecture (or some variant)

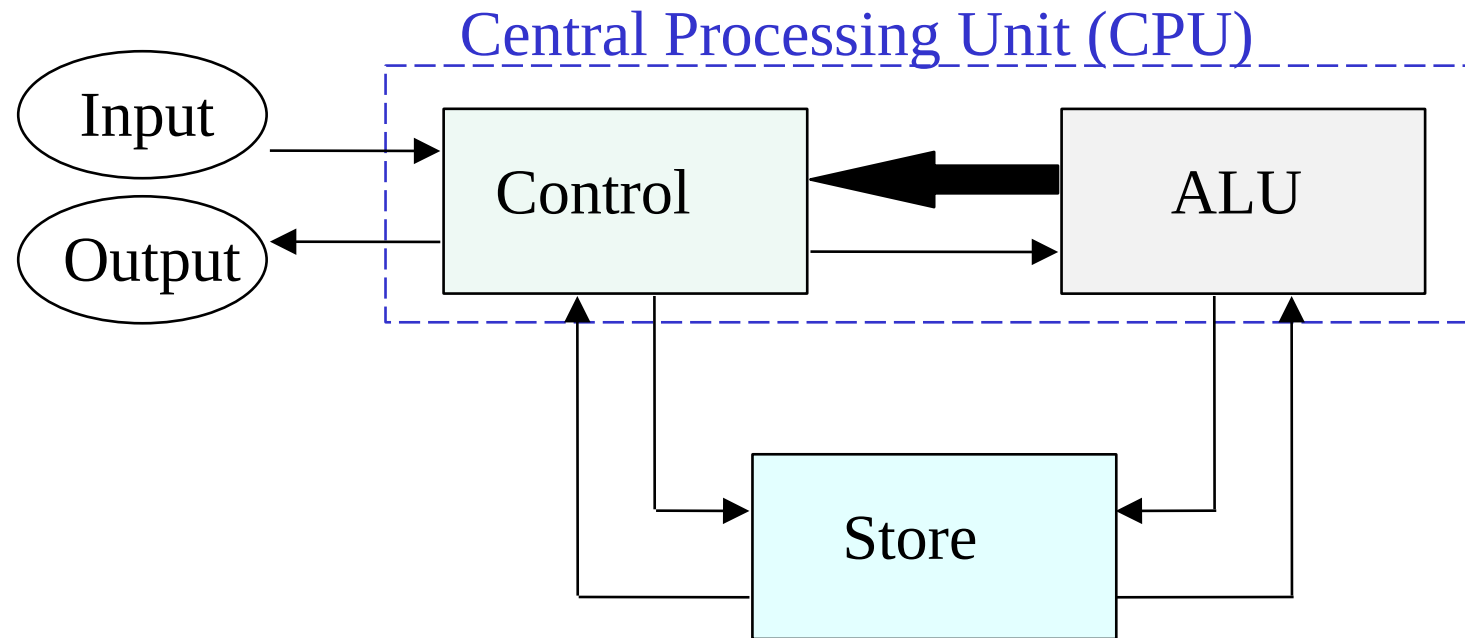

## The von Neumann Architecture: I/O

We still need communication between the machine and the outside world, using *input* and *output* devices

## The complete computer system

Operation sequencing can be controlled **directly** by the **state of the ALU** (which is fed back to the control unit) - in particular *prompts* when an operation is finished:
